is as illustrated in the Fig. 2.1. Find the corner frequencies  $\omega_{01}$  and  $\omega_{02}$  from the plot.

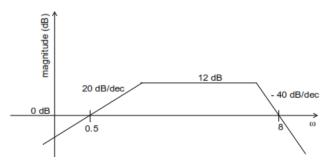

Fig. 2.1

**Solution:** The corner frequencies can be calculated as follows:

$$slope = \frac{M_2 - M_1}{log\omega_2 - log\omega_1}$$

Therefore for  $\omega_{02}$ ,

$$-40 = \frac{0 - 12}{\log 8 - \log \omega_{02}}$$

$$log8 - log\omega_{02} = \frac{12}{40}$$

$$log\omega_{02} = log8 - \frac{12}{40}$$

$$\omega_{02} = 4$$

And for  $\omega_{01}$ ,

$$20 = \frac{0 - 12}{log0.5 - log\omega_{01}}$$

$$log0.5 - log\omega_{01} = \frac{-12}{20}$$
 (2.1.2)

$$log\omega_{01} = log0.5 + \frac{12}{20}$$

$$\omega_{01} = 2$$

So, the corner frequencies are  $\omega_{01}$ =2 and  $\omega_{02}$ 

2.2. Find the transfer function from the calculated frequencies.

**Solution:** By looking to the plot, we can say

that since the initial slope is +20, there must be a zero at the origin.

At  $\omega_{01}$ , the change in slope is -20dB, so their exists one pole at this frequency.

At  $\omega_{02}$ , the change in slope is -40dB, so their exists two pole at this frequency.

The denominators have the form  $(1 + \frac{3}{\omega})$ So, the denominator of the transfer function is  $(1 + \frac{s}{2})(1 + \frac{s}{4})^2$ Therefore, the transfer function is,

$$\frac{cs}{(1+\frac{s}{2})(1+\frac{s}{4})^2}$$

here c is some constant

2.3. Compare the above calculated transfer function with one of the options that best represents it.

$$(A)\frac{2s}{(1+0.5s)(1+0.25s)^2} \quad (B)\frac{4(1+0.5s)}{s(1+0.25s)}$$

$$(C)\frac{2s}{(1+2s)(1+4s)} \quad (D)\frac{4s}{(1+2s)(1+4s)^2}$$

Solution: From the above given option, we can see that option (A) best represents our transfer function.

$$\frac{2s}{(1+0.5s)(1+0.25s)^2}$$

2.4. Verify the above plot by plotting the transfer function.

**Solution:** The bode plot is Fig. 2.4:

The plot was plotted using the following code:

import numpy as np import control.matlab as ml import matplotlib.pyplot as plt

# If using termux import subprocess import shlex #end if

# num is the numerator of the trasfer function which is (2s)

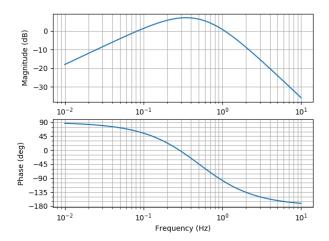

Fig. 2.4: Plot of G(s)

```
# dem is the denominator of the transfer
    function which is (0.25s + 1)(0.25s + 1)
    (0.5s + 1)
num = np.array([2, 0])
den = np.polymul(np.array([0.5, 1]), np.array
    ([0.25, 1])
den = np.polymul(den, np.array([0.25, 1]))
# Generating the transfer function
g = ml.tf(num, den)
print("The transfer function is: ", g)
print("The poles of the above function are",
    ml.pole(g))
print("The zeros of the above function are",
    ml.zero(g)
# Generating the bode plot as well as plotting
mag, phase, w = ml.bode(g)
# If using termux
plt.savefig("./figs/ep18btech11016 plot.pdf")
plt.savefig("./figs/ep18btech11016 plot.eps")
subprocess.run(shlex.split("termux-open ./figs
    /ep18btech11016 plot.pdf"))
# else
plt.show()
